25 In process variants (v) and (xiii) (second variant) the reaction is a standard amide or urea formation reaction involving e.g.:

1. Activation of a carboxylic acid (e.g. to an acid chloride, mixed anhydride, active ester, O-acyl-isourea or other species), and treatment with an amine (Ogliaruso, M.A.; Wolfe, J.F. in *The Chemistry of Functional Groups (Ed. Patai, S.) Suppl. B: The Chemistry of Acid Derivatives, Pt. 1* (John Wiley and Sons, 1979), pp 442-8; Beckwith, A.L.J. in *The Chemistry of Functional Groups (Ed. Patai, S.) Suppl. B: The Chemistry of Amides (Ed. Zabricky, J.)* (John Wiley and Sons, 1970), p 73 ff. The acid and amine are preferably reacted in the presence of an activating agent such as 1-(dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDC) or 1-hydroxybenzotriazole (HOBT) or O-(7-azabenzotriazol-1-yl)-N,N,N',N'-tetramethyluronium hexafluorophosphate (HATU); or
- 30 2. The specific methods of:
  - a. *in situ* conversion of an acid into the amine component by a modified Curtius reaction procedure (Shioiri, T., Murata, M., Hamada, Y., *Chem. Pharm. Bull.* 1987, 35, 2698)
- 35

b. *in situ* conversion of the acid component into the acid chloride under neutral conditions (Villeneuve, G. B.; Chan, T. H., *Tetrahedron. Lett.* 1997, 38, 6489).

A' may be, for example, protected hydroxymethylene.

5 The process variant (xiii) (third variant) is a standard addition reaction using methods well known to those skilled in the art. The process is preferably carried out in a polar organic solvent e.g. acetonitrile in the presence of an organic base e.g. triethylamine.

10 In process variant (xiii) (fourth variant) the coupling may be effected in acetonitrile at room temperature in the presence of one equivalent of lithium perchlorate as catalyst (general method of J.E. Chateaufneuf *et al*, *J. Org. Chem.*, 56, 5939-5942, 1991) or more preferably with ytterbium triflate in dichloromethane. In some cases an elevated temperature such as 40 – 70 °C may be beneficial. Alternatively, the compound of formula (V) may be treated with a base, such as one equivalent of butyl lithium, and the resulting salt reacted with the oxirane in an inert solvent such as tetrahydrofuran, 15 preferably at an elevated temperature such as 80°C. Use of a chiral epoxide will afford single diastereomers. Alternatively, mixtures of diastereomers may be separated by preparative HPLC or by conventional resolution through crystallisation of salts formed from chiral acids.

20 The process variant (xii) is a standard urea or carbamate formation reaction from the reaction of an isocyanate with an amine or alcohol and is conducted by methods well known to those skilled in the art (for example see March, J; *Advanced Organic Chemistry, Edition 3* (John Wiley and Sons, 1985), p802-3). The process is preferably carried out in a polar solvent such as N,N-dimethylformamide.

25 In process variant (i) the process is two step: firstly a condensation using a base, preferably sodium hydride or alkoxide, sodamide, alkyl lithium or lithium dialkylamide, preferably in an aprotic solvent e.g. ether, THF or benzene; secondly, hydrolysis using an inorganic acid, preferably HCl in aqueous organic solvent at 0-100°C. Analogous routes are described in DE330945, EP31753, EP53964 and H. Sargent, *J. Am. Chem. Soc.* 68, 2688-2692 (1946). Similar Claisen methodology is described in Soszko *et. al.*, 30 *Pr.Kom.Mat. Przyr.Poznan.Tow.Przyj.Nauk.*, (1962), 10, 15.

In process variant (ii) the reaction is carried out in the presence of a base, preferably organometallic or metal hydride e.g. NaH, lithium diisopropylamide or NaOEt, preferably in an aprotic solvent, preferably THF, ether or benzene at -78 to 25°C (analogous process in Gutswiller *et al.* (1978) *J. Am. Chem. Soc.* 100, 576).

35 In process variants (iii) and (iv) if a base is used it is preferably NaH, KH, an alkyl lithium e.g. BuLi, a metal alkoxide e.g. NaOEt, sodamide or lithium dialkylamide e.g. di-

isopropylamide. An analogous method is described in US 3989691 and M.Gates et. al. (1970) J. Amer.Chem.Soc., 92, 205, as well as Taylor et al. (1972) JACS 94, 6218.

In process variant (vi) the reaction is a standard reductive alkylation using, e.g., sodium borohydride or sodium triacetoxymethylborohydride (Gribble, G. W. in *Encyclopedia of Reagents for Organic Synthesis* (Ed. Paquette, L. A.) (John Wiley and Sons, 1995), p 4649).

The process variant (vii) is a standard alkylation reaction well known to those skilled in the art, for example where an alcohol or amine is treated with an alkyl halide in the presence of a base (for example see March, J; *Advanced Organic Chemistry, Edition 3* (John Wiley and Sons, 1985), p364-366 and p342-343). The process is preferably carried out in a polar solvent such as N,N-dimethylformamide

In process variant (xiii) (first variant) the reaction is a standard sulphonamide formation reaction well known to those skilled in the art. This may be e.g. the reaction of a sulphonyl halide with an amine.

In process variant (viii) where X is W such as halogen, methanesulphonyloxy or trifluoromethanesulphonyloxy, the hydroxy group in Y is preferably converted to an OM group where M is an alkali metal by treatment of an alcohol with a base. The base is preferably inorganic such as NaH, lithium diisopropylamide or sodium. Where X is OH, the hydroxy group in Y is activated under Mitsunobu conditions (Fletcher et.al. J Chem Soc. (1995), 623). Alternatively the X=O and Y=CH<sub>2</sub>OH groups can be reacted directly by activation with 1,3-dicyclohexylcarbodiimide (DCC) (Chem. Berichte 1962, 95, 2997 or Angewante Chemie 1963 75, 377).

In process variant (ix) the reaction is conducted in the presence of an organic base such as triethylamine or pyridine such as described by Fuhrman et.al., J. Amer. Chem. Soc.; 67, 1245, 1945. The X=NR<sup>11'</sup> or Y=SO<sub>2</sub>W intermediates can be formed from the requisite amine e.g. by reaction with SO<sub>2</sub>Cl<sub>2</sub> analogously to the procedure described by the same authors Fuhrman et.al., J. Amer. Chem. Soc.; 67, 1245, 1945.

In process variant (x) where one of X and Y contains NHR<sup>11</sup> the leaving group W is halogen and the reaction is a standard amine formation reaction such as direct alkylation described in (Malpass, J. R., in *Comprehensive Organic Chemistry*, Vol. 2 (Ed. Sutherland, I. O.), p 4 ff.) or aromatic nucleophilic displacement reactions (see references cited in *Comprehensive Organic Chemistry*, Vol. 6, p 946-947 (reaction index); Smith, D. M. in *Comprehensive Organic Chemistry*, Vol. 4 (Ed. Sammes, P. G.) p 20 ff.). This is analogous to the methods described in GB 1177849.

In process variant (x) where one of X and Y contains OH or SH, this is preferably converted to an OM or SM group where M is an alkali metal by treatment of an alcohol, thiol or thioacetate with a base. The base is preferably inorganic such as NaH, lithium

diisopropylamide or sodium, or, for SH, metal alkoxide such as sodium methoxide. The X/Y group containing the thioacetate SCOR<sup>x</sup> is prepared by treatment of an alcohol or alkyl halide with thioacetic acid or a salt thereof under Mitsunobu conditions. The leaving group V is a halogen. The reaction may be carried out as described in Chapman et.al., J. Chem Soc., (1956), 1563, Gilligan et. al., J. Med. Chem., (1992), 35, 4344, Aloup et. al., J. Med. Chem. (1987), 30, 24, Gilman et al., J.A.C.S. (1949), 71, 3667 and Clinton et al., J.A.C.S. (1948), 70, 491, Barluenga et al., J. Org. Chem. (1987) 52, 5190. Alternatively where X is OH and Y is CH<sub>2</sub>W, W is a hydroxy group activated under Mitsunobu conditions (Fletcher et.al. J Chem Soc. (1995), 623).

10 In process variant (xi) the reaction is as described in den Hertzog et. al., *recl.Trav. Chim. Pays-Bas*, (1950), 69, 700.

In process variant (xiv) the leaving group W is preferably chloro or trifluoromethylsulphonyl and the reaction is the palladium catalysed process known as the "Buchwald" reaction (J. Yin and S. L. Buchwald, *Org.Lett.*, 2000, 2, 1101).

15 In process variant (xv) the leaving group W is preferably trifluoromethylsulphonyl and the reaction is known as the "Heck" reaction (Heck, *Comp. Org. Syn.* Vol 4 Ch4.3 p.833).

In process variant (xvi) coupling of the acetylene compound (V) with the compound (IV), where the leaving group X is preferably trifluoromethylsulphonyl or halide, is accomplished using standard Pd-mediated chemistry, for example using Pd(Ph<sub>3</sub>P)<sub>2</sub>Cl<sub>2</sub> as the catalyst along with the addition of CuI in a mixture of triethylamine and dimethylformamide. Hydrogenation of the intermediate -C≡C- group is carried out conventionally over a suitable catalyst eg Pd/C, either partially to -CH=CH- or fully to -CH<sub>2</sub>-CH<sub>2</sub>-.

25 In process variant (xvii) the amine X is NHR<sup>1</sup> is deprotonated with a strong base such as sodium hydride or potassium tert-butoxide followed by reaction with an oxirane (V), where Y and R<sup>3</sup> together are oxygen and n = 1.

Reduction of a carbonyl group A or B to CHOH can be readily accomplished using reducing agents well known to those skilled in the art, e.g. sodium borohydride in aqueous ethanol or lithium aluminium hydride in ethereal solution. This is analogous to methods described in EP53964, US384556 and J. Gutzwiller *et al*, *J. Amer. Chem. Soc.*, 1978, 100, 576.

30 The carbonyl group A or B may be reduced to CH<sub>2</sub> by treatment with a reducing agent such as hydrazine in ethylene glycol, at e.g. 130-160°C, in the presence of potassium hydroxide.

35 Reaction of a carbonyl group A or B with an organometallic reagent yields a group where R<sup>6</sup> or R<sup>8</sup> is OH and R<sup>7</sup> or R<sup>9</sup> is alkyl.

A hydroxy group on A or B may be oxidised to a carbonyl group by oxidants well known to those skilled in the art, for example, manganese dioxide, pyridinium chlorochromate or pyridinium dichromate.

5 A hydroxyalkyl A-B group  $\text{CHR}^7\text{CR}^9\text{OH}$  or  $\text{CR}^7(\text{OH})\text{CHR}^9$  may be dehydrated to give the group  $\text{CR}^7=\text{CR}^9$  by treatment with an acid anhydride such as acetic anhydride.

Methods for conversion of  $\text{CR}^7=\text{CR}^9$  by reduction to  $\text{CHR}^7\text{CHR}^9$  are well known to those skilled in the art, for example using hydrogenation over palladium on carbon as catalyst. Methods for conversion of  $\text{CR}^7=\text{CR}^9$  to give the A-B group  $\text{CR}^7(\text{OH})\text{CHR}^9$  or  $\text{CHR}^7\text{CR}^9\text{OH}$  are well known to those skilled in the art for example  
10 by epoxidation and subsequent reduction by metal hydrides, hydration, hydroboration or oxymercuration.

An amide carbonyl group may be reduced to the corresponding amine using a reducing agent such as lithium aluminium hydride.

A hydroxy group in A or B may be converted to azido by activation and  
15 displacement e.g. under Mitsunobu conditions using hydrazoic acid or by treatment with diphenylphosphorylazide and base, and the azido group in turn may be reduced to amino by hydrogenation.

Examples of groups  $\text{Z}^1, \text{Z}^2, \text{Z}^3, \text{Z}^4, \text{Z}^5$ , are  $\text{CR}^{1a'}$  where  $\text{R}^{1a'}$  is a group convertible to  $\text{R}^{1a}$ .  $\text{Z}^1, \text{Z}^2, \text{Z}^3, \text{Z}^4$  and  $\text{Z}^5$  are preferably  $\text{Z}^1, \text{Z}^2, \text{Z}^3, \text{Z}^4$  and  $\text{Z}^5$ .

20  $\text{R}^{1a'}$  and  $\text{R}^{1'}$  are preferably  $\text{R}^{1a}$  and  $\text{R}^1$ .  $\text{R}^{1'}$  is preferably methoxy.  $\text{R}^{3'}$  is preferably  $\text{R}^3$  or with  $\text{R}^w$  is a bond,  $\text{R}^{3'1}$  is  $\text{R}^3_1$  or more preferably hydrogen, vinyl, alkoxy carbonyl or carboxy.  $\text{R}^{4'}$  is  $\text{R}^4$  or more preferably H or an N-protecting group such as t-butoxycarbonyl, benzyloxycarbonyl or 9-fluorenylmethyloxycarbonyl.

Conversions of  $\text{R}^{1a'}$ ,  $\text{R}^{1'}$ ,  $\text{R}^{3'}$  and  $\text{R}^{4'}$  and interconversions of  $\text{R}^{1a}$ ,  $\text{R}^1$ ,  $\text{R}^3_1$ ,  $\text{R}^3$  and  $\text{R}^4$  are conventional. In compounds which contain an optionally substituted hydroxy group, suitable conventional hydroxy protecting groups which may be removed without disrupting the remainder of the molecule include acyl and alkylsilyl groups. N protecting groups are removed by conventional methods.

For example  $\text{R}^{1'}$  methoxy is convertible to  $\text{R}^{1'}$  hydroxy by treatment with lithium  
30 and diphenylphosphine (general method described in Ireland et. al. (1973) J.Amer.Chem.Soc., 7829) or HBr. Alkylation of the hydroxy group with a suitable alkyl derivative bearing a leaving group such as halide and a protected amino, piperidyl, amidino or guanidino group or group convertible thereto, yields, after conversion/deprotection,  $\text{R}^1$  alkoxy substituted by optionally N-substituted amino,  
35 piperidyl, guanidino or amidino.

$R^3$  or  $R^3_1$  alkenyl is convertible to hydroxyalkyl by hydroboration using a suitable reagent such as 9-borabicyclo[3.3.1]nonane, epoxidation and reduction or oxymercuration.

5  $R^3$  or  $R^3_1$  1,2-dihydroxyalkyl can be prepared from  $R^3$  alkenyl using osmium tetroxide or other reagents well known to those skilled in the art (see Advanced Organic Chemistry (*Ed. March, J.*) (John Wiley and Sons, 1985), p 732-737 and refs. cited therein) or epoxidation followed by hydrolysis (see Advanced Organic Chemistry (*Ed. March, J.*) (John Wiley and Sons, 1985), p 332,333 and refs. cited therein).

10  $R^3$  or  $R^3_1$  vinyl can be chain extended by standard homologation e.g by conversion to hydroxyethyl followed by oxidation to the aldehyde which is then subjected to a Wittig reaction.

Opening an epoxide  $R^3$  or  $R^3_1$  group with cyanide anion yields a  $CH(OH)-CH_2CN$  group.

15 Opening an epoxide-containing  $R^3$  or  $R^3_1$  group with azide anion yields an  $\alpha$ -hydroxy azide derivative which can be reduced to the  $\alpha$ -hydroxy amine. Conversion of the  $\alpha$ -hydroxy amine to a carbamate is followed by ring closure with base to give the 2-oxo-oxazolidinyl containing  $R^3$  or  $R^3_1$  group.

20 Substituents on  $R^3$  or  $R^3_1$  alkyl or alkenyl may be interconverted by conventional methods, for example hydroxy may be derivatised by esterification, acylation or etherification. Hydroxy groups may be converted to halogen, thiol, alkylthio, azido, alkylcarbonyl, amino, aminocarbonyl, oxo, alkylsulphonyl, alkenylsulphonyl or aminosulphonyl by conversion to a leaving group and substitution by the required group, hydrolysis or oxidation as appropriate or reaction with an activated acid, isocyanate or alkoxyisocyanate. Primary and secondary hydroxy groups can be oxidised to an aldehyde or ketone respectively and alkylated with a suitable agent such as an organometallic

25 reagent to give a secondary or tertiary alcohol as appropriate. A carboxylate group may be converted to an hydroxymethyl group by reduction of an ester of this acid with a suitable reducing agent such as lithium aluminium hydride.

30 Substituted 2-oxo-oxazolidinyl containing  $R^3$  or  $R^3_1$  groups may be prepared from the corresponding aldehyde by conventional reaction with a glycine anion equivalent, followed by cyclisation of the resulting amino alcohol (M Grauert et al, Ann Chem (1985) 1817, Rozenberg et al, Angew Chem Int Ed Engl (1994) 33(1) 91). The resulting 2-oxo-oxazolidinyl group contains a carboxy group which can be converted to other  $R^{10}$  groups by standard procedures.

35 Carboxy groups within  $R^3$  or  $R^3_1$  may be prepared by Jones' oxidation of the corresponding alcohols  $CH_2OH$  using chromic acid and sulphuric acid in water/methanol (E.R.H. Jones et al, J.C.S. 1946,39). Other oxidising agents may be used for this

transformation such as sodium periodate catalysed by ruthenium trichloride (G.F.Tutwiler *et al*, J.Med.Chem., 1987, 30(6), 1094), chromium trioxide-pyridine (G. Just *et al*, Synth. Commun. 1979, 9(7), 613), potassium permanganate (D.E.Reedich *et al*, J. Org. Chem., 1985, 50(19), 3535, and pyridinium chlorochromate (D. Askin *et al*, Tetrahedron Letters, 1988, 29(3), 277.

The carboxy group may alternatively be formed in a two stage process, with an initial oxidation of the alcohol to the corresponding aldehyde using for instance dimethyl sulphoxide activated with oxalyl chloride (N.Cohen *et al*, J. Am. Chem. Soc., 1983, 105, 3661) or dicyclohexylcarbodiimide (R.M.Wengler, Angew. Chim. Int. Ed. Eng., 1985, 24(2), 77), or oxidation with tetrapropylammonium perruthenate (Ley *et al*, J. Chem.Soc. Chem Commun., 1987, 1625). The aldehyde may then be separately oxidised to the corresponding acid using oxidising agents such as silver (II) oxide (R.Grigg *et al*, J. Chem. Soc. Perkin1, 1983, 1929), potassium permanganate (A.Zurcher, Helv. Chim. Acta., 1987, 70 (7), 1937), sodium periodate catalysed by ruthenium trichloride (T.Sakata *et al*, Bull. Chem. Soc. Jpn., 1988, 61(6), 2025), pyridinium chlorochromate (R.S.Reddy *et al*, Synth. Commun., 1988, 18(51), 545) or chromium trioxide (R.M.Coates *et al*, J. Am. Chem. Soc., 1982, 104, 2198).

An  $R^3$  or  $R^3_1$   $CO_2H$  group may also be prepared from oxidative cleavage of the corresponding diol,  $CH(OH)CH_2OH$ , using sodium periodate catalysed by ruthenium trichloride with an acetonitrile-carbontetrachloride-water solvent system (V.S.Martin *et al*, Tetrahedron Letters, 1988, 29(22), 2701).

$R^3$  or  $R^3_1$  groups containing a cyano or carboxy group may also be prepared by conversion of an alcohol to a suitable leaving group such as the corresponding tosylate by reaction with para-toluenesulphonyl chloride (M.R.Bell, J. Med. Chem., 1970, 13, 389), or the iodide using triphenylphosphine, iodine, and imidazole (G. Lange, Synth. Commun., 1990, 20, 1473). The second stage is the displacement of the leaving group with cyanide anion (L.A.Paquette *et al*, J. Org. Chem., 1979, 44 (25), 4603; P.A.Grieco *et al*, J. Org. Chem., 1988, 53 (16), 3658). Finally acidic hydrolysis of the nitrile group gives the desired acids (H.Rosemeyer *et al*, Heterocycles, 1985, 23 (10), 2669). The hydrolysis may also be carried out with base e.g. potassium hydroxide (H.Rapoport, J. Org. Chem., 1958, 23, 248) or enzymatically (T. Beard *et al*, Tetrahedron Asymmetry, 1993, 4 (6), 1085).

$R^3$  fluoro groups may be prepared from the compound where  $R^3$  is hydroxy by reaction with a fluorodeoxygenating reagent such as DAST (diethylaminosulfur trifluoride).

Other functional groups in  $R^3$  or  $R^3_1$  may be obtained by conventional conversions of carboxy or cyano groups.

Tetrazoles are conveniently prepared by reaction of sodium azide with the cyano group (e.g. F. Thomas et al, Bioorg. Med. Chem. Lett., 1996, 6 (6), 631; K.Kubo et al, J. Med. Chem., 1993, 36,2182) or by reaction of azidotri-n-butyl stannane with the cyano group followed by acidic hydrolysis ( P.L.Ornstein, J. Org. Chem., 1994, 59, 7682 and J. Med. Chem, 1996, 39 (11), 2219).

The 3-hydroxy-3-cyclobutene-1,2-dione-4-yl group (e.g. R.M.Soll, Bioorg. Med. Chem. Lett., 1993, 3 (4), 757 and W. A. Kinney, J. Med. Chem., 1992, 35 (25), 4720) can be prepared by the following sequence:- (1) a compound where R<sub>3</sub> is (CH<sub>2</sub>)<sub>n</sub>CHO (n = 0,1,2) is treated with triethylamine, carbon tetrabromide/triphenylphosphine to give initially (CH<sub>2</sub>)<sub>n</sub>CH=CBBr<sub>2</sub>; (2) dehydrobromination of this intermediate to give the corresponding bromoethyne derivative (CH<sub>2</sub>)<sub>n</sub>C≡CBr (for this 2 stage sequence see D. Grandjean et al, Tetrahedron Letters, 1994, 35 (21), 3529); (3) palladium-catalysed coupling of the bromoethyne with 4-(1-methylethoxy)-3-(tri-n-butylstannyl)cyclobut-3-ene-1,2-dione (Liebeskind et al, J. Org. Chem., 1990, 55, 5359); (4) reduction of the ethyne moiety to -CH<sub>2</sub>CH<sub>2</sub>- under standard conditions of hydrogen and palladium on charcoal catalysis(see Howard et al, Tetrahedron, 1980, 36, 171); and finally (4) acidic hydrolysis of the methylethoxyester to generate the corresponding 3-hydroxy-3-cyclobutene-1,2-dione group (R.M.Soll, Bioorg. Med. Chem. Lett., 1993, 3 (4), 757).

The tetrazol-5-ylaminocarbonyl group may be prepared from the corresponding carboxylic acid and 2-aminotetrazole by dehydration with standard peptide coupling agents such as 1,1'-carbonyldiimidazole (P. L. Ornstein et al, J. Med Chem, 1996, 39 (11), 2232).

The alkyl- and alkenyl-sulphonylcarboxamides are similarly prepared from the corresponding carboxylic acid and the alkyl- or alkenyl-sulphonamide by dehydration with standard peptide coupling agents such as 1,1'-carbonyldiimidazole (P. L. Ornstein et al, J. Med. Chem., 1996, 39 (11), 2232).

The hydroxamic acid groups are prepared from the corresponding acids by standard amide coupling reactions eg N. R. Patel et al, Tetrahedron, 1987, 43 (22), 5375

2,4-thiazolidinedione groups may be prepared from the aldehydes by condensation with 2,4-thiazolidinedione and subsequent removal of the olefinic double bond by hydrogenation.

The preparation of 5-oxo-1,2,4-oxadiazoles from nitriles is described by Y.Kohara et al, Bioorg. Med. Chem. Lett., 1995, 5(17), 1903.

1,2,4-triazol-5-yl groups may be prepared from the corresponding nitrile by reaction with an alcohol under acid conditions followed by reaction with hydrazine and then an R<sup>10</sup>-substituted activated carboxylic acid (see JB Polya in 'Comprehensive

Heterocyclic Chemistry' Edition 1 p762, Ed AR Katritzky and CW Rees, Pergamon Press, Oxford 1984 and J.J. Ares et al, J. Heterocyclic Chem., 1991, 28(5), 1197).

Novel intermediates of formula (VI):

5 where the variables are as defined in formula (I), also form part of the invention.

The piperidine NH is converted to NR<sup>4</sup> by conventional means such as amide or sulphonamide formation, or by alkylation, for example by reaction with a vinyl derivative and heating in an alcohol such as ethanol containing an acid such as acetic acid, with an alkyl halide or other reactive alkyl derivative in the presence of base, acylation/reduction  
 10 or reductive alkylation with an aldehyde. For example where R<sup>4</sup> is a group -U-V-R<sup>5</sup><sub>2</sub> an acyl derivative R<sup>5</sup><sub>2</sub>V'COW or R<sup>5</sup><sub>2</sub>V'SO<sub>2</sub>W, may be used for compounds where U is CO or SO<sub>2</sub> or, where U and V are CH<sub>2</sub>, by reaction with a vinyl derivative R<sup>5</sup><sub>2</sub>-CH=CH<sub>2</sub>, for example by heating in an alcohol such as ethanol containing an acid such as acetic acid, alkylation with an alkyl halide R<sup>5</sup><sub>2</sub>-V'-CH<sub>2</sub>-halide or alkyl derivative R<sup>5</sup><sub>2</sub>-V'-CH<sub>2</sub>-W in  
 15 the presence of base, acylation/reduction or reductive alkylation with an aldehyde R<sup>5</sup>-V'-CHO where V' is V or a group convertible thereto such as a dimethyl acetal or 1,3-dithiane. Such groups are deprotected by conventional means eg dimethyl acetal by hydrolysis using dilute acid in tetrahydrofuran, and 1,3-dithiane using HgCl<sub>2</sub> in aqueous acetonitrile (Marshall J. A. et al., J. Org. Chem. 34, 4188 (1969) or AgNO<sub>2</sub> and I<sub>2</sub> in  
 20 tetrahydrofuran (Nishide K. et al., Heterocycles 44(1) 393 (1997).

Where V is a group CR<sup>17</sup>R<sup>18</sup> and R<sup>18</sup> is H this may be obtained by reduction of a V = CO group followed by derivatisation of the resulting R<sup>17</sup> = OH group as necessary.

Where R<sup>4</sup> is -CH<sub>2</sub>R<sup>5</sup><sub>1</sub> it may be introduced by alkylation with an alkyl halide or other alkyl derivative R<sub>4</sub>-W in the presence of base, acylation/reduction or reductive  
 25 alkylation with an aldehyde.

Where R<sup>4</sup> is a group -U<sup>a</sup>-X<sup>1a</sup>-X<sup>2a</sup>-X<sup>3a</sup>-X<sup>4a</sup> other examples of R<sup>4'</sup> convertible to R<sup>4</sup> include N-protecting groups and -U<sup>a</sup>-CH<sub>2</sub>-CO<sub>2</sub>H which may be reacted with an amine X<sup>4a</sup>-NH<sub>2</sub> in the presence of a coupling agent such as 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDC) to give R<sup>4</sup>=-U<sup>a</sup>-CH<sub>2</sub>-CO-NH-X<sup>4a</sup>. This reaction may be  
 30 carried out on the compound of formula (V) or after coupling (IV) and (V). An oxiranylmethyl group may be introduced by reaction with epichlorohydrin, and the resulting oxirane opened with a suitable amine X<sup>4a</sup>-NH<sub>2</sub> to give an R<sup>4</sup> group of the form -CH<sub>2</sub>-CH(OH)-CH<sub>2</sub>-NH-X<sup>4a</sup>. Cyclisation of the hydroxy and amino (R<sup>14a</sup> and R<sup>13a</sup>)

groups may be effected with phosgene in base.  $R^4$  groups of the form  $-\text{CH}_2-\text{CH}_2-\text{NH}-\text{X}^{3a}-\text{X}^{4a}$  may be introduced by alkylation of the piperidine NH. A flexible synthesis involves the introduction of an intermediate group  $-\text{CH}_2-\text{CH}_2-\text{NH}_2$  by treatment with a 2-haloethylcarbamic acid ester followed by reduction. The intermediate group can then be acylated or alkylated as required to introduce the  $-\text{X}^{3a}-\text{X}^{4a}$  group.  $R^4$  groups where  $\text{X}^{3a}$  is O may be prepared from the  $\text{X}^{4a}$ -oxirane reacted with an  $R^{4'}\text{CH}_2\text{CH}_2\text{OH}$  group in the presence of lithium perchlorate.

Interconversion of substituents on the aromatic group  $\text{X}^{4a}$  may be carried out conventionally at any appropriate point in the synthesis. For example pyridine may be oxidised to the the N-oxide with and oxidising agent such as meta-chloroperoxybenzoic acid, hydrogen peroxide or t-butyl hydroperoxide after protection of any other nitrogen atoms. N-oxides may be rearranged in trifluoroacetic acid to give the hydroxypyridines.

A group  $\text{V}'$  is CO may be converted to an oxime or oxime derivative  $\text{C}=\text{NOR}^{19}$  by reaction with hydroxylamine or substituted hydroxylamine  $\text{NH}_2\text{OR}^{19}$  by heating in the presence of sodium acetate, for instance in an alcohol solvent such as methanol. The E- and Z-oximes may be separated by crystallisation or by conventional chromatography.

Where one of  $R^3$  and  $R^6$ ,  $R^7$ ,  $R^8$  or  $R^9$  contains a carboxy group and the other contains a hydroxy or amino group they may together form a cyclic ester or amide linkage. This linkage may form spontaneously during coupling of the compounds of formulae (IV) and (V) or in the presence of standard peptide coupling agents.

It will be appreciated that under certain circumstances interconversions may interfere, for example, hydroxy groups in A or B and the piperidine NH will require protection e.g. as a carboxy- or silyl-ester group for hydroxy and as an acyl derivative for nitrogen, during conversion of  $R^{1a'}$ ,  $R^{1'}$ ,  $R^{2'}$ ,  $R^{3'}$ ,  $R^{3'1}$  or  $R^{4'}$ , or during the coupling of the compounds of formulae (IV) and (V).

Compounds of formulae (IV) and (V) are known compounds, (see for example Smith *et al.*, *J. Amer. Chem. Soc.*, 1946, 68, 1301) or prepared analogously, see for example the references cited above.

Compounds of formula (IV) where X is  $\text{CR}^6\text{R}^7\text{SO}_2\text{W}$  may be prepared by a route analogous to that of Ahmed El Hadri *et al.*, *J. Heterocyclic Chem.*, 1993, 30(3), 631. Thus compounds of formula (IV) where X is  $\text{CH}_2\text{SO}_2\text{OH}$  may be prepared by reacting the corresponding 4-methyl compound with N-bromosuccinimide, followed by treatment with sodium sulfite. The leaving group W may be converted to another leaving group W, e.g. a halogen group, by conventional methods.

The isocyanate of formula (IV) may be prepared conventionally from a 4-amino derivative such as 4-amino-quinoline, and phosgene, or phosgene equivalent (eg triphosgene) or it may be prepared more conveniently from a 4-carboxylic acid by a "one-

pot" Curtius Reaction with diphenyl phosphoryl azide (DPPA) [see T. Shiori et al. *Chem. Pharm. Bull.* **35**, 2698-2704 (1987)].

The 4-amino derivatives are commercially available or may be prepared by conventional procedures from a corresponding 4-chloro or 4-trifluoromethanesulphonate derivative by treatment with ammonia (O.G. Backeberg et. al., *J. Chem Soc.*, 381, 1942) or propylamine hydrochloride (R. Radinov et. al., *Synthesis*, 886, 1986).

4-Alkenyl compounds of formula (IV) may be prepared by conventional procedures from a corresponding 4-halogeno-derivative by e.g. a Heck synthesis as described in e.g. *Organic Reactions*, 1982, 27, 345.

4-Halogeno derivatives of compounds of formula (IV) are commercially available, or may be prepared by methods known to those skilled in the art. A 4-chloroquinoline is prepared from the corresponding quinolin-4-one by reaction with phosphorus oxychloride ( $\text{POCl}_3$ ) or phosphorus pentachloride,  $\text{PCl}_5$ . A 4-chloroquinazoline is prepared from the corresponding quinazolin-4-one by reaction with phosphorus oxychloride ( $\text{POCl}_3$ ) or phosphorus pentachloride,  $\text{PCl}_5$ . A quinazolinone and quinazolines may be prepared by standard routes as described by T.A. Williamson in *Heterocyclic Compounds*, 6, 324 (1957) Ed. R.C. Elderfield.

Activated carboxy derivatives  $\text{X}=\text{A}'\text{COW}$  of formula (IV) may be prepared from  $\text{X}=\text{A}'\text{CO}_2\text{H}$  derivatives in turn prepared from  $\text{CO}_2\text{H}$  derivatives by conventional methods such as homologation.

4-Carboxy derivatives of compounds of formula (IV) are commercially available or may be prepared by conventional procedures for preparation of carboxy heteroaromatics well known to those skilled in the art. For example, quinazolines may be prepared by standard routes as described by T.A. Williamson in *Heterocyclic Compounds*, 6, 324 (1957) Ed. R.C. Elderfield. These 4-carboxy derivatives may be activated by conventional means, e.g. by conversion to an acyl halide or anhydride.

4-Carboxy derivatives such as esters may be reduced to hydroxymethyl derivatives with for example lithium aluminium hydride. Reaction with mesyl chloride and triethylamine would give the mesylate derivative. A diazo compound ( $\text{X}$  is  $-\text{CH}=\text{N}_2$ ) may be prepared from the 4-carboxaldehyde via the tosyl hydrazone. The 4-carboxaldehyde may be obtained from the acid by standard procedures well known to those skilled in the art.

A 4-oxirane derivative of compounds of formula (IV) is conveniently prepared from the 4-carboxylic acid by first conversion to the acid chloride with oxalyl chloride and then reaction with trimethylsilyldiazomethane to give the diazoketone derivative. Subsequent reaction with 5M hydrochloric acid gives the chloromethylketone. Reduction with sodium borohydride in aqueous methanol gives the chlorohydrin which undergoes

ring closure to afford the epoxide on treatment with base, e.g. potassium hydroxide in ethanol-tetrahydrofuran.

Alternatively and preferably, 4-oxirane derivatives can be prepared from bromomethyl ketones which can be obtained from 4-hydroxy compounds by other routes well known to those skilled in the art. For example, hydroxy compounds can be converted to the corresponding 4-trifluoromethanesulphonates by reaction with trifluoromethanesulphonic anhydride under standard conditions (see K. Ritter, *Synthesis*, 1993, 735). Conversion into the corresponding butyloxyvinyl ethers can be achieved by a Heck reaction with butyl vinyl ether under palladium catalysis according to the procedure of W. Cabri *et al*, *J. Org. Chem*, 1992, **57** (5), 1481. (Alternatively, the equivalent intermediates can be attained by Stille coupling of the trifluoromethanesulphonates or the analogous chloro derivatives with (1-ethoxyvinyl)tributyl tin (T. R. Kelly, *J. Org. Chem.*, 1996, **61**, 4623).) The alkyloxyvinyl ethers are then converted into the corresponding bromomethylketones by treatment with N-bromosuccinimide in aqueous tetrahydrofuran in a similar manner to the procedures of J. F. W. Keana, *J. Org. Chem.*, 1983, **48**, 3621 and T. R. Kelly, *J. Org. Chem.*, 1996, **61**, 4623.

The 4-hydroxyderivatives can be prepared from an aminoaromatic by reaction with methylpropiolate and subsequent cyclisation, analogous to the method described in N. E. Heindel *et al*, *J. Het. Chem.*, 1969, **6**, 77. For example, 5-amino-2-methoxy pyridine can be converted to 4-hydroxy-6-methoxy-[1,5]naphthyridine using this method.

If a chiral reducing agent such as (+) or (-)-B-chlorodiisopinocampheylborane ['DIP-chloride'] is substituted for sodium borohydride, the prochiral chloromethylketone is converted into the chiral chlorohydrin with ee values generally 85-95% [see C. Bolm *et al*, *Chem. Ber.* **125**, 1169-1190, (1992)]. Recrystallisation of the chiral epoxide gives material in the mother liquor with enhanced optical purity (typically ee 95%).

The (*R*)-epoxide, when reacted with an amine derivative gives ethanolamine compounds as single diastereomers with (*R*)-stereochemistry at the benzylic position.

Alternatively, the epoxide may be prepared from the 4-carboxaldehyde by a Wittig approach using trimethylsulfonium iodide [see G.A. Epling and K-Y Lin, *J. Het. Chem.*, 1987, **24**, 853-857], or by epoxidation of a 4-vinyl derivative.

Pyridazines may be prepared by routes analogous to those described in *Comprehensive Heterocyclic Chemistry*, Volume 3, Ed A.J. Boulton and A. McKillop and naphthyridines may be prepared by routes analogous to those described in *Comprehensive Heterocyclic Chemistry*, Volume 2, Ed A.J. Boulton and A. McKillop.

4-Hydroxy-1,5-naphthyridines can be prepared from 3-aminopyridine derivatives by reaction with diethyl ethoxymethylene malonate to produce the 4-hydroxy-3-carboxylic acid ester derivative with subsequent hydrolysis to the acid, followed by

thermal decarboxylation in quinoline (as for example described for 4-Hydroxy-[1,5]naphthyridine-3-carboxylic acid, J. T. Adams *et al.*, *J. Amer. Chem. Soc.*, 1946, 68, 1317). A 4-hydroxy-[1,5]naphthyridine can be converted to the 4-chloro derivative by heating in phosphorus oxychloride, or to the 4-methanesulphonyloxy or 4-trifluoromethanesulphonyloxy derivative by reaction with methanesulphonyl chloride or trifluoromethanesulphonic anhydride, respectively, in the presence of an organic base. A 4-amino 1,5-naphthyridine can be obtained from the 4-chloro, 4-methanesulphonyloxy or 4-trifluoromethanesulphonyloxy derivative by reaction with n-propylamine in pyridine.

Similarly, 6-methoxy-1,5-naphthyridine derivatives can be prepared from 3-amino-6-methoxypyridine.

1,5-Naphthyridines may be prepared by other methods well known to those skilled in the art (for examples see P.A. Lowe in "Comprehensive Heterocyclic Chemistry" Volume 2, p581-627, Ed A.R. Katritzky and C.W. Rees, Pergamon Press, Oxford, 1984).

The 4-hydroxy and 4-amino-cinnolines may be prepared following methods well known to those skilled in the art [see A.R. Osborn and K. Schofield, *J. Chem. Soc.* 2100 (1955)]. For example, a 2-aminoacetophenone is diazotised with sodium nitrite and acid to produce the 4-hydroxycinnoline with conversion to chloro and amino derivatives as described for 1,5-naphthyridines.

The compounds of formula (V) are either commercially available or may be prepared by conventional methods.

For compounds of formula (V), where Y is  $\text{NHR}^{11'}$  suitable amines may be prepared from a 4-substituted piperidine or tetrahydropyridine acid or alcohol. In a first instance, an N-protected piperidine or tetrahydropyridine containing an acid bearing substituent, can undergo a Curtius rearrangement and the intermediate isocyanate can be converted to a carbamate by reaction with an alcohol. Conversion to the amine may be achieved by standard methods well known to those skilled in the art used for amine protecting group removal. For example, an acid substituted N-protected piperidine or tetrahydropyridine can undergo a Curtius rearrangement e.g. on treatment with diphenylphosphoryl azide and heating, and the intermediate isocyanate reacts in the presence of 2-trimethylsilylethanol to give the trimethylsilylethylcarbamate (T.L. Capson & C.D. Poulter, *Tetrahedron Lett.*, 1984, 25, 3515). This undergoes cleavage on treatment with tetrabutylammonium fluoride to give the 4-amine substituted N-protected compound of formula (V). Alternatively, an acid group  $(\text{CH}_2)_n\text{CO}_2\text{H}$  may be converted to  $(\text{CH}_2)_n\text{NHR}^{11'}$  by reaction with an activating agent such as isobutyl chloroformate followed by an amine  $\text{R}^{11'}\text{NH}_2$  and the resulting amide reduced with a reducing agent such as  $\text{LiAlH}_4$ .

In a second instance, an N-protected piperidine or tetrahydropyridine containing an alcohol bearing substituent undergoes a Mitsunobu reaction (for example as reviewed in Mitsunobu, *Synthesis*, (1981), 1), for example with succinimide in the presence of diethyl azodicarboxylate and triphenylphosphine to give the phthalimidoethylpiperidyl- or tetrahydropiperidyl amine. Removal of the phthaloyl group, for example by treatment with methylhydrazine, gives the amine of formula (V).

Compounds of formula (V) where  $n=1$  may be prepared from the compound where  $n=0$  by homologation eg starting from a compound of formula (V) where  $Y=CO_2H$ .

Compounds of formula (V) where Y is a carboxylic acid or derivative, substituted by  $R^3$  at the 4-position may be prepared from a 4-keto derivative via a cyanohydrin reaction with sodium cyanide/hydrochloric acid, or more conveniently using trimethylsilylcyanide in dichloromethane, followed by hydrolysis by heating in conc. hydrochloric acid to give the  $\alpha$ -hydroxy acid (Compound(V),  $Y=CO_2H$ ,  $n=0$ ,  $R^{3'}=OH$ ).

The same keto-derivative could undergo a Wittig reaction with  $Ph_3PCH=CO_2Me$  to give the  $\alpha\beta$ -unsaturated carboxylic ester  $MeO_2C-CH=C<Ring$ , which could be epoxidised (eg meta-chloroperbenzoic acid) to give the  $\alpha,\beta$ -epoxy-ester. Alternatively this could be formed directly from the keto-derivative via a glycidic ester condensation with an  $\alpha$ -halogeno-ester. Base hydrolysis would afford the  $\alpha,\beta$ -epoxy-carboxylic acid, which on reduction (eg lithium triethylborohydride – see J. Micklefield et al J. Amer. Chem. Soc. 117, 1153-1154 (1995) or hydrogenation over platinum oxide (see Artamonov Zh.Obshch.Khim. 28 1355-1359 (1958)) would afford the  $\beta$ -hydroxy acid (Compound (V)  $Y=CO_2H$ ,  $n=1$ ,  $R^{3'}=OH$ ). Alternatively a Reformatsky reaction with the keto-derivative and an  $\alpha$ -bromocarboxylic acid ester and zinc, followed by acid hydrolysis would afford the  $\beta$ -hydroxycarboxylic acid directly.

The keto-derivative could also undergo a Strecker type synthesis via a Bucherer-Bergs procedure (potassium cyanide/ammonium carbonate) [see T. Scott Yokum et al. Tetrahedron Letters, 38, 4013-4016 (1997)] to give the  $\alpha$ -amino-carboxylic acid (Compound (V)  $Y=CO_2H$ ,  $n=0$ ,  $R^{3'}=NH_2$ ).

The keto derivative ( $R^{4'}$  is a protecting group) can be reacted with the lithium anion derived from trimethylsilyl acetylene and n-butyl lithium followed by removal of the trimethylsilyl group by conventional methods eg using  $K_2CO_3$  and MeOH, to give the acetylenic alcohol (Compound (V)  $Y=C\equiv CH$ ,  $n=0$ ,  $R^{3'}=OH$ ).

Compounds of formula (V) with  $Y=C\equiv CH$ ,  $n=0$ ,  $R^{3'}=F$ ) may be prepared from the protected keto derivative using the general method of van Niel and Collins, *J. Med. Chem.*, 1999, 42, 2087-2104.

Compounds of formula (V) with a  $Y = -CONHR^{11'}$  group may be prepared from the corresponding nitrile by partial hydrolysis with concentrated mineral acid at ambient temperature, such as concentrated hydrochloric acid (M. Brown *et al*, J. Med. Chem., 1999, 42, (9), 1537) or with concentrated sulphuric acid (F. Macias *et al*

5 Tetrahedron, 2000, 56, (21), 3409).

Compounds of formula (V) with a  $Y = -OCONH_2$  group may be prepared from the corresponding alcohol by reaction with phosgene followed by ammonia.

Compounds with  $Y = CO_2H$  may be converted to a  $-CONH_2$  group by conversion to an 'active ester' for example by reaction with N-hydroxysuccinimide to give the  
10 succinimide ester, which on reaction with ammonia gives the amide  $-CONH_2$ .

Compounds of formula (V) with a  $Y = -CH=CH_2$  group and  $n=0$  may be prepared by reaction of vinyl lithium or vinyl Grignard with a ketone ((V) where  $Y(CH_2)_n-$  and  $R^{3'}$  are together =O).

Compounds of formula (V) where  $R^3$  and  $R^{3_1}$  are both hydroxy and oriented trans  
15 may be prepared from a tetrahydropyridine by conversion to an epoxide (for example reaction with meta-chloroperbenzoic acid) followed by hydrolysis. The corresponding cis-diol may be prepared from the tetrahydropyridine by reaction with osmium tetroxide, preferably with a co-oxidant such as N-methyl morpholine oxide. The above epoxide may be opened with an amine or azide (followed by conversion of the azide to amino by,  
20 for example, hydrogenation) to introduce a nitrogen-substituent at position-3.

Compounds of formula (V) where  $R^{3_1}$  is fluoro may be prepared by reaction of the epoxide with HF/pyridine [see F. Pasqui *et al* *Tetrahedron*, 52, 185-198 (1996)].

Compounds where  $R^3$  is fluoro may be prepared from the compound where  $R^3$  is hydroxy by reaction with a fluorodeoxygenating reagent such as DAST

25 (diethylaminosulfur trifluoride).

Compounds where  $R^3$  is a carboxylic acid or derivative may be prepared from a N-protected piperidine-4,4-dicarboxylic acid diester, for example a tert-butyl, methyl diester by base hydrolysis of the methyl ester. Compounds where  $R^3$  is carboxamide may be prepared from a diester by reaction with ammonia. Compounds where  $R^3$  is a tert-  
30 butyl ester may be converted later in the synthesis to compounds where  $R^3$  is carboxylic acid, which may be further modified, eg by conversion to carboxamide, or by reduction to hydroxymethyl. N-protected piperidine-4,4-dicarboxylic diesters or 4-cyano-4-carboxylic esters may be prepared by reaction of a malonic acid diester or cyanoacetic acid ester with an intermediate  $(WCH_2CH_2)_2NR^{4'}$  where W is a leaving group eg Cl or  
35 Br, in the presence of a base eg  $K_2CO_3$  or NaH (S. Huybrechts and G.J. Hoornaert, Synth. Commun., 1981, 11,17).

Compounds where  $R^3$  is alkyl may be prepared from compounds where  $R^3$  is hydrogen by treatment with a strong base, such as lithium diisopropylamide, and quenching with an alkyl halide, such as methyl iodide. Compounds where  $R^3$  is  $CF_3$  may be prepared by quenching with 5-(trifluoromethyl)dibenzothiophenium

5 trifluoromethanesulfonate. Alternatively, quenching the anion with an electrophilic fluorinating reagent such as 1-chloromethyl-4-fluoro-1,4-diazoniabicyclo[2.2.2]octane bis(tetrafluoroborate) will give compounds where  $R^3$  is fluoro.

Compounds where  $R^3$  is hydroxy or amino may be alkylated (eg with an alkyl halide such as methyl iodide) or acylated (for example with acetyl chloride) to give  
10 compounds where  $R^3$  is alkoxy, acyloxy, alkylamino or acylamino.

Compounds of formula (V) where  $R^3_1$  is in the 2-position can be prepared from 4-oxopiperidine 2-carboxylic acid by converting the 2-carboxylic acid to  $R^3_1$  and then transforming the 4-ketone to an appropriate  $Y(CH_2)_n/R_3$  moiety such as a hydroxycarboxylic acid (via the cyanohydrin) or aminocarboxylic acid (via a Strecker  
15 type synthesis).

Compounds of formula (V) with a 3-hydroxyl group may be prepared from a 3,4 oxirane-piperidine carboxylic acid by reaction with an amine  $NHR^2$  or azide (followed by conversion of the azide to amino). [See for example K. Krajewski et al. Tetrahedron Asymmetry 10, 4591-4598 (1999)].

20  $R^{5_2}$ -V'- $CH_2$ -halides and  $R^{5_2}$ -V'- $CH_2$ -W derivatives, acyl derivatives  $R^{5_2}V'COW$  and  $R^{5_2}V'SO_2W$ , vinyl derivatives  $R^{5_2}-CH_2=CH_2$ , alkyl derivatives  $R^{5_2}$ -V'- $CH_2$ -W or aldehydes  $R^{5_2}$ -V'-CHO are commercially available or are prepared conventionally. The aldehydes may be prepared by partial reduction of the  $R^{5_2}$ -V'-ester with lithium aluminium hydride or di-isobutylaluminium hydride or more preferably by  
25 reduction to the alcohol, with lithium aluminium hydride or sodium borohydride (see *Reductions by the Alumino- and Borohydrides in Organic Synthesis*, 2nd ed., Wiley, N.Y., 1997; *JOC*, 3197, 1984; *Org. Synth. Coll.*, 102, 1990; 136, 1998; *JOC*, 4260, 1990; *TL*, 995, 1988; *JOC*, 1721, 1999; *Liebigs Ann./Recl.*, 2385, 1997; *JOC*, 5486, 1987), followed by oxidation to the aldehyde with manganese (II) dioxide, or by a 'Swern' procedure (oxalyl chloride/DMSO), or by using potassium dichromate (PDC). The aldehydes may also be prepared from carboxylic acids in two stages by conversion to a mixed anhydride for example by reaction with isobutyl chloroformate followed by  
30 reduction with sodium borohydride (R. J. Alabaster et al., *Synthesis*, 598, 1989) to give the alcohols and then oxidation with a standard oxidising agent such as pyridinium dichromate or by homologation of the  $R^{5_2}CHO$  intermediate. Acyl derivatives  $R^{5_2}V'COW$  may be prepared by activation of the  $R^{5_2}$ -V'-acid.  $R^{5_2}$ -V'- $CH_2$ -halides such as bromides may be prepared from the alcohol  $R^{5_2}$ -V'- $CH_2OH$  by reaction with  
35

phosphorus tribromide in DCM/triethylamine, DMF or pyridine.  $R^5_2-V'-CH_2-W$  derivatives such as methanesulphonyl derivatives may be prepared from the alcohol  $R^5_2-V'-CH_2OH$  by reaction with methane sulphonyl chloride in DCM/triethylamine.  $R^5_2-V'SO_2W$  derivatives may be prepared by a route analogous to that of Ahmed El Hadri *et al*, *J. Heterocyclic Chem.*, 1993, 30(3), 631. Thus compounds of formula

5  $R^5_2CH_2SO_2OH$  may be prepared by reacting the corresponding  $R^5_2CH_3$  compound with N-bromosuccinimide, followed by treatment with sodium sulfite. The leaving group W may be converted to another leaving group W, e.g. a halogen group, by conventional methods. The  $R^5_2-V'-U-$  derivatives may be prepared by various conventional strategies.

10 For example the homologous aldehyde  $R^5_2-CHO$  may be treated with trimethylsulfonium methylsulfate in basic conditions, to give an epoxide intermediate (see *Synth. Commun.*, 749, 1985) which is then treated with lewis acid, such as trifluoroboron etherate or diethyl etherate, to provide the desired aldehyde (see *JOC*, 1720, 1999). The aldehyde  $R^5_2-CHO$  could also be treated with an appropriate phosphonium salt, such as

15 (methoxymethyl)triphenylphosphonium chloride, in a Wittig fashion reaction. The resulting enol ether can readily be hydrolysed to homologous aldehydes (*Chem. Ber.*, 2514, 1962).  $R^5_2-COW$  derivatives can be converted to the aldehyde  $R^5_2-V'-CHO$  in several steps (see *JACS*, 1325, 1986). The  $R^5_2COCH_2$ -halide derivatives may be prepared by standard methods from the  $R^5_2CO_2H$  derivative, for example, by acid

20 chloride formation, conversion to the alpha-diazoketone with diazomethane and reaction with a halogen acid to provide the halomethylketone. Vinyl derivatives  $R^5-CH=CH_2$  may be prepared from the corresponding diethylaminoethyl derivative by quaternisation with dimethyl sulphate and heating, resulting in elimination of the charged amino group. The diethylaminoethyl derivative may be prepared from another ethyl derivative eg the

25 hydroxyethyl by conventional amine formation. Alternatively, it may be prepared from a methyl derivative by condensation with diethylamine and formaldehyde.

Vinyl compounds  $R^5_2-CH_2=CH_2$  may be prepared by olefination of an aldehyde by a Peterson-type olefination, or by a Wittig reaction, or by reaction of a halo-compound with tributyl vinyl tin in the presence of a palladium catalyst eg  $Pd(Ph_3P)_4$ .

30 Other  $R^4$ -halides and  $R^4-W$  derivatives, vinyl derivatives  $X^{4a}-X^{3a}-CH=CH_2$ , acyl derivatives such as  $X^{4a}-X^{3a}-X^{2a}-X^{1a}-Ua-W$  and  $X^{4a}-X^{3a}-X^{2a}-X^{1a}-SO_2W$  or aldehydes  $X^{4a}-X^{3a}-X^{2a}-X^{1a}-CHO$  are commercially available or are prepared conventionally. The aldehydes may be prepared by partial reduction of the corresponding ester with lithium aluminium hydride or di-isobutylaluminium hydride or more preferably

35 by reduction to the alcohol, with lithium aluminium hydride or sodium borohydride (see *Reductions by the Alumino- and Borohydrides in Organic Synthesis*, 2nd ed., Wiley, N.Y., 1997; *JOC*, 3197, 1984; *Org. Synth. Coll.*, 102, 1990; 136, 1998; *JOC*, 4260, 1990;

TL, 995, 1988; JOC, 1721, 1999; Liebigs Ann./Recl., 2385, 1997; JOC, 5486, 1987), followed by oxidation to the aldehyde with manganese (II) dioxide, or by a 'Swern' procedure (oxalyl chloride/DMSO), or by using potassium dichromate (PDC). The aldehydes may also be prepared from carboxylic acids in two stages by conversion to a mixed anhydride for example by reaction with isobutyl chloroformate followed by reduction with sodium borohydride (R. J. Alabaster et al., Synthesis, 598, 1989) to give the hydroxymethyl substituted heteroaromatic or aromatic and then oxidation with a standard oxidising agent such as pyridinium dichromate or manganese (II) dioxide. Acyl derivatives may be prepared by activation of the corresponding ester. R<sup>4</sup>-halides such as bromides may be prepared from the alcohol R<sup>4</sup>OH by reaction with phosphorus tribromide in dichloromethane/triethylamine. Where X<sup>2a</sup> is CO and X<sup>3a</sup> is NR<sup>13a</sup> the R<sup>4</sup>-halide may be prepared by coupling an X<sup>4a</sup>-NH<sub>2</sub> amine and Br-(CH<sub>2</sub>)<sub>2</sub>COBr. Vinyl derivatives X<sup>4a</sup>-X<sup>3a</sup>-CH=CH<sub>2</sub> may be prepared from the corresponding diethylaminoethyl derivative by quaternisation with dimethyl sulphate and heating, resulting in elimination of the charged amino group. The diethylaminoethyl derivative may be prepared from another ethyl derivative eg the hydroxyethyl by conventional amine formation. Alternatively, it may be prepared from a methyl derivative by condensation with diethylamine and formaldehyde. R<sup>4</sup>-W derivatives such as methanesulphonyl derivatives may be prepared from the alcohol R<sup>4</sup>OH by reaction with methane sulphonyl chloride. The leaving group W may be converted to another leaving group W, e.g. a halogen group, by conventional methods.

Where R<sup>5</sup><sub>2</sub> is an optionally substituted benzoimidazol-2-yl group, the compound of formula (V) where R<sup>4'</sup> is R<sup>4</sup> may be obtained by converting a R<sup>4'</sup> cyanomethyl group with partial hydrolysis to give the 2-ethoxycarbonimidoyl group which can then be condensed with an appropriately substituted 1,2-diaminobenzene to give the required benzoimidazol-2-yl group.

R<sup>5</sup><sub>2</sub>H heterocycles are commercially available or may be prepared by conventional methods.

For example where a benzoxazinone is required, a nitrophenol may be alkylated with for example ethyl bromoacetate and the resulting nitro ester reduced with Fe in acetic acid (alternatively Zn/AcOH/HCl or H<sub>2</sub>/Pd/C or H<sub>2</sub>/Raney Ni). The resulting amine may undergo spontaneous cyclisation to the required benzoxazinone, or cyclisation may be induced by heating in acetic acid. Alternatively a nitrophenol may be reduced to the aminophenol, which is reacted with chloroacetyl chloride [method of X. Huang and C. Chan, *Synthesis* 851 (1994)] or ethyl bromoacetate in DMSO [method of Z. Moussavi et al. *Eur. J. Med. Chim. Ther.* 24, 55-60 (1989)]. The same general routes can be applied to prepare benzothiazinones [See for example F. Eiden and F. Meinel, *Arch. Pharm.* 312,

302-312 (1979), H. Fenner and R Grauert *Liebigs. Ann. Chem.* 193-313 (1978)]. A variety of routes are available to prepare aza analogues of benzothiazinones via the key corresponding aldehydes. For instance, 2-oxo-2,3-dihydro-1*H*-pyrido[3,4-*b*][1,4]thiazine-7-carbaldehyde may be accessed from 5-fluoro-2-picoline (E. J. Blanz, F. A. French, J. R. DoAmaral and D. A. French, *J. Med. Chem.* 1970, 13, 1124-1130) by constructing the thiazinone ring onto the pyridyl ring then functionalising the methyl substituent. The dioxin analogue of this aza substitution pattern, 2,3-dihydro-[1,4]dioxino[2,3-*c*]pyridine-7-carbaldehyde is accessible from Kojic acid by aminolysis from pyrone to pyridone then annelating the dioxin ring. Other aza substitution patterns with pyridothiazin-3-one, pyridooxazin-3-one, and pyridodioxin ring systems are also accessible. Ortho-aminothiophenols may be conveniently prepared and reacted as their zinc complexes [see for example V. Taneja et al *Chem. Ind.* 187 (1984)]. Benzoxazolones may be prepared from the corresponding aminophenol by reaction with carbonyl diimidazole, phosgene or triphosgene. Reaction of benzoxazolones with diphosphorus pentasulfide affords the corresponding 2-thione. Thiazines and oxazines can be prepared by reduction of the corresponding thiazinone or oxazinone with a reducing agent such as lithium aluminium hydride.

Conversions of  $R^w$ ,  $R^{1a'}$ ,  $R^{1'}$ ,  $R^{3'}$ ,  $R^{3'1}$  and  $R^{4'}$  may be carried out on the intermediates of formulae (IV) and (V) prior to their reaction to produce compounds of formula (I) in the same way as described above for conversions after their reaction.

The pharmaceutical compositions of the invention include those in a form adapted for oral, topical or parenteral use and may be used for the treatment of bacterial infection in mammals including humans.

The antibiotic compounds according to the invention may be formulated for administration in any convenient way for use in human or veterinary medicine, by analogy with other antibiotics.

The composition may be formulated for administration by any route, such as oral, topical or parenteral. The compositions may be in the form of tablets, capsules, powders, granules, lozenges, creams or liquid preparations, such as oral or sterile parenteral solutions or suspensions.

The topical formulations of the present invention may be presented as, for instance, ointments, creams or lotions, eye ointments and eye or ear drops, impregnated dressings and aerosols, and may contain appropriate conventional additives such as preservatives, solvents to assist drug penetration and emollients in ointments and creams.

The formulations may also contain compatible conventional carriers, such as cream or ointment bases and ethanol or oleyl alcohol for lotions. Such carriers may be

present as from about 1% up to about 98% of the formulation. More usually they will form up to about 80% of the formulation.

Tablets and capsules for oral administration may be in unit dose presentation form, and may contain conventional excipients such as binding agents, for example syrup, acacia, gelatin, sorbitol, tragacanth, or polyvinylpyrrolidone; fillers, for example lactose, sugar, maize-starch, calcium phosphate, sorbitol or glycine; tableting lubricants, for example magnesium stearate, talc, polyethylene glycol or silica; disintegrants, for example potato starch; or acceptable wetting agents such as sodium lauryl sulphate. The tablets may be coated according to methods well known in normal pharmaceutical practice. Oral liquid preparations may be in the form of, for example, aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, or may be presented as a dry product for reconstitution with water or other suitable vehicle before use. Such liquid preparations may contain conventional additives, such as suspending agents, for example sorbitol, methyl cellulose, glucose syrup, gelatin, hydroxyethyl cellulose, carboxymethyl cellulose, aluminium stearate gel or hydrogenated edible fats, emulsifying agents, for example lecithin, sorbitan monooleate, or acacia; non-aqueous vehicles (which may include edible oils), for example almond oil, oily esters such as glycerine, propylene glycol, or ethyl alcohol; preservatives, for example methyl or propyl p-hydroxybenzoate or sorbic acid, and, if desired, conventional flavouring or colouring agents.

Suppositories will contain conventional suppository bases, e.g. cocoa-butter or other glyceride.

For parenteral administration, fluid unit dosage forms are prepared utilizing the compound and a sterile vehicle, water being preferred. The compound, depending on the vehicle and concentration used, can be either suspended or dissolved in the vehicle. In preparing solutions the compound can be dissolved in water for injection and filter sterilised before filling into a suitable vial or ampoule and sealing.

Advantageously, agents such as a local anaesthetic, preservative and buffering agents can be dissolved in the vehicle. To enhance the stability, the composition can be frozen after filling into the vial and the water removed under vacuum. The dry lyophilized powder is then sealed in the vial and an accompanying vial of water for injection may be supplied to reconstitute the liquid prior to use. Parenteral suspensions are prepared in substantially the same manner except that the compound is suspended in the vehicle instead of being dissolved and sterilization cannot be accomplished by filtration. The compound can be sterilised by exposure to ethylene oxide before suspending in the sterile vehicle. Advantageously, a surfactant or wetting agent is included in the composition to facilitate uniform distribution of the compound.

The compositions may contain from 0.1% by weight, preferably from 10-60% by weight, of the active material, depending on the method of administration. Where the compositions comprise dosage units, each unit will preferably contain from 50-500 mg of the active ingredient. The dosage as employed for adult human treatment will preferably range from 100 to 3000 mg per day, for instance 1500 mg per day depending on the route and frequency of administration. Such a dosage corresponds to 1.5 to 50 mg/kg per day. Suitably the dosage is from 5 to 20 mg/kg per day.

No toxicological effects are indicated when a compound of formula (I) or a pharmaceutically acceptable salt or *in vivo* hydrolysable ester thereof is administered in the above-mentioned dosage range.

The compound of formula (I) may be the sole therapeutic agent in the compositions of the invention or a combination with other antibiotics or with a  $\beta$ -lactamase inhibitor may be employed.

Compounds of formula (I) are active against a wide range of organisms including both Gram-negative and Gram-positive organisms.

The following examples illustrate the preparation of certain compounds of formula (I) and the activity of certain compounds of formula (I) against various bacterial organisms.
